

NEXAMART — AI CUSTOMER SUPPORT AGENT DEPLOYMENT

Self-Directed Business Analysis Case Study | 2026

02 — MOST Analysis

Mission • Objectives • Strategy • Tactics

1. Purpose of the Analysis

Following the SWOT Analysis, the MOST framework is used to translate NexaMart's current business situation into a clear strategic direction for the proposed AI-powered customer support transformation.

MOST examines four interconnected dimensions:

- Mission — What is the organization ultimately trying to achieve?
- Objectives — What specific business outcomes should be achieved?
- Strategy — What overall approach will be used to achieve those objectives?
- Tactics — What practical initiatives and actions will execute the strategy?

For this case study, MOST is applied to the proposed introduction of an AI-powered customer support agent while maintaining appropriate human involvement for complex, sensitive, or low-confidence interactions.

2. Business Context

NexaMart is a fictional multinational e-commerce organization exploring the use of an AI-powered customer support agent.

The proposed transformation is intended to address repetitive customer enquiries, response-time pressure, fragmented information retrieval, and the need to provide scalable customer support.

The preceding SWOT Analysis identified potential opportunities associated with AI-enabled support, while also highlighting risks involving inaccurate responses, data privacy, integration complexity, customer trust, and inadequate AI governance.

The MOST Analysis therefore focuses on establishing strategic alignment before detailed process design and solution requirements are developed.

3. MOST Analysis

3.1 MISSION

Mission Statement

Improve NexaMart's customer support capability by using AI to provide faster, consistent, scalable assistance for routine customer interactions while preserving appropriate human oversight for complex, sensitive, or low-confidence cases.

Business Analysis Interpretation

The mission deliberately focuses on the business outcome rather than the technology. The objective is not simply to "implement an AI chatbot." The proposed AI capability should contribute to a broader improvement in customer support effectiveness, scalability, accessibility, and service quality. This

distinction provides a strategic basis for evaluating whether individual AI capabilities are actually aligned with the organization's business needs.

3.2 OBJECTIVES

Objective 1 — Improve Response Speed

Enable customers to receive timely responses to common enquiries such as order information, product questions, policies, and other routine requests.

Objective 2 — Reduce Repetitive Support Workload

Automate suitable, high-volume and repeatable interactions so human support agents can focus on cases requiring judgement, investigation, empathy, or exception handling.

Objective 3 — Improve Response Consistency

Provide standardized responses based on approved, maintained, and governed knowledge sources.

Objective 4 — Extend Support Availability

Provide customers with access to basic support outside traditional customer-service operating hours.

Objective 5 — Establish Controlled Human Escalation

Ensure interactions are transferred to human agents when the AI lacks sufficient confidence, encounters sensitive situations, or reaches the limits of its permitted scope.

Objective 6 — Establish Appropriate Governance

Ensure customer information, AI responses, access controls, monitoring, escalation, and operational controls are appropriately governed before wider deployment.

4. Strategy

Strategic Direction

NexaMart should pursue a controlled, phased AI-support strategy rather than immediate full automation.

The strategic approach should be based on the following principles:

Process-first assessment — Identify and prioritize customer-support processes according to volume, complexity, business value, customer impact, and automation feasibility.

Knowledge-first enablement — Establish a reliable and governed knowledge foundation before allowing the AI agent to provide customer-facing responses.

Controlled integration — Assess and implement only the system integrations required for the AI agent to retrieve permitted information and support defined customer-service workflows.

Human-in-the-loop design — Maintain human involvement for complex, sensitive, low-confidence, exceptional, or out-of-scope interactions.

Phased implementation — Begin with a controlled pilot covering selected use cases before considering broader deployment.

Measurement and continuous improvement — Monitor operational, customer, quality, and risk indicators and use the findings to refine the solution and determine whether further automation is justified.

5. Tactics

Area	Proposed Tactic
Process Analysis	Map the current customer-support process and identify repetitive, high-volume, exception-heavy, and automation-suitable interactions.
Knowledge Management	Review, validate, structure, and govern the information that the AI agent would use when responding to customers.
Requirements	Define functional, non-functional, security, data, integration, escalation, and reporting requirements.
AI Scope	Establish which enquiry types the AI may handle independently and which require human intervention.
System Integration	Assess required integration points with relevant CRM, order-management, knowledge-management, and customer-service systems.
Escalation	Define confidence thresholds, exception-handling rules, escalation triggers, and human hand-off procedures.
Pilot	Conduct a controlled pilot using selected customer-support scenarios and defined success criteria.
Governance	Establish appropriate controls for access, monitoring, response quality, data protection, auditability, and ongoing AI performance review.
Measurement	Define KPIs covering response time, automation rate, escalation rate, resolution quality, customer experience, and operational impact.
Continuous Improvement	Review pilot results and continuously refine processes, knowledge, requirements, and AI behaviour before expanding the solution.

6. Strategic Alignment

The MOST analysis establishes the following strategic chain:

MISSION

Improve customer support capability through scalable, consistent, and appropriately governed AI-enabled assistance.

OBJECTIVES

Improve response speed, reduce repetitive workload, improve consistency, extend availability, establish controlled escalation, and maintain appropriate governance.

STRATEGY

Adopt a process-first, phased AI transformation with reliable knowledge, controlled integration, human oversight, and measurable outcomes.

TACTICS

Analyse processes, establish knowledge controls, define requirements, identify suitable AI use cases, design escalation, conduct a pilot, monitor performance, and continuously improve.

7. BA Interpretation and Key Findings

Finding 1 — The technology is an enabler, not the business objective.

The proposed AI agent should be evaluated against measurable business and customer-service outcomes rather than technology adoption alone.

Finding 2 — Automation suitability must be assessed at process level.

Not every customer-support interaction should be automated. Process characteristics, customer impact, complexity, risk, and exception frequency should influence automation decisions.

Finding 3 — Human escalation is part of the solution design.

The target operating model should not assume that AI replaces human support. Instead, the AI and human-support functions should operate as a controlled service model with clearly defined boundaries.

Finding 4 — Governance must be considered before deployment.

Data access, response quality, security, monitoring, escalation, and accountability should be incorporated into the transformation rather than treated as post-implementation activities.

Finding 5 — The transformation should be measurable.

Clear success criteria and KPIs are required to determine whether the proposed solution is delivering the intended business value.

8. Assumptions and Validation Points

The following items are currently treated as assumptions or areas requiring further investigation:

- NexaMart has sufficient historical customer-support information to identify common enquiry types.
- Relevant customer-support knowledge can be validated and maintained.
- Existing systems may provide integration capabilities required by the proposed solution.
- Suitable customer-support processes can be identified for an initial AI pilot.
- Appropriate data-access and security controls can be established.
- Human support capacity will remain available for escalated interactions.

These assumptions should be validated during subsequent Business Analysis activities rather than treated as confirmed facts.

9. Link to the Next BA Technique

The MOST Analysis establishes the strategic direction, but it does not yet explain how NexaMart's customer-support work is performed.

The next stage is therefore to examine the current-state process.

The Business Process Modelling analysis will investigate:

- How a customer enquiry enters the support process
- Which teams or systems participate
- Where information is retrieved
- Where hand-offs occur
- Where delays or bottlenecks may occur
- Which activities are repetitive
- Where exceptions and escalations occur
- Where AI or other automation could potentially be introduced

This will provide the foundation for comparing the current-state process with a potential future-state process.

10. Conclusion

The MOST Analysis translates the findings from the SWOT Analysis into a coherent strategic direction for NexaMart's proposed AI-powered customer support transformation.

The analysis establishes that the transformation should not be approached as an immediate technology deployment. Instead, NexaMart should first understand the business processes, define appropriate objectives, establish governance and requirements, identify suitable automation opportunities, and introduce the capability through a controlled and measurable approach.

The next analysis will therefore move from strategic alignment to operational understanding through Business Process Modelling.

Case Study Classification

Self-directed / simulated Business Analysis case study. NexaMart is a fictional organization created for portfolio and educational purposes. The analysis does not represent work performed for an actual NexaMart engagement.
